

Technical Note for Replication: 8.3 Filenames

Rishav Roy

1 Technical Note for Replication

Those replicating the code for this paper are encouraged to skim the code chunk titled `Define functions to read in short 8.3 filenames`. There the functions `read_sav_short()`, `read_csv_short()`, and `read_excel_short()` are defined; if the replicator runs into issues while reading in files, troubleshooting methods are explained there.

```

# ---TROUBLESHOOTING---
# If getting "file does not exist" or similar errors:
# Switch the function used to read in the file e.g., if the relevant file is being read in u

# If that didn't work and you're not using Windows:
# Either modify this code chunk for your OS (note the "if" statement at the start of each fu

# ---

# Purpose of this chunk:
# To ensure R can identify and read in all necessary files.
# This project found me making frequent use of file paths over 260 characters in length. Out
# This code chunk turns our long name inputs into 8.3 filenames while tricking the read_*()-

# Context for nerds:
# In my Registry Editor, under Computer\HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control
# But none of that mattered! Windows File Explorer lacks a longPathAware entry in its .exe f
# It's possible that setting NtfsDisable8dot3NameCreation=0 would've prevented all of this c

# ---

```
